

Back End

- This mostly remains completely unchanged only small changes have been made to accommodate FE design
- LongBlob object type was chosen for how to store Images in the Data Base

Front End

Scenes

- All scenes for the main app are mostly complete, the following need work:
 - orderHistory.fxml
 - adminView.fxml
- Other than these the main source of work needed to be done on scenes is aesthetic

Controllers

- Most controllers are done except for the aforementioned scene's controllers
- The OrderHistoryController will be implementing the Google Maps API rather than where it was originally
 - It's currently in the listingViewController just so that I could see if it works and it does
 - The GoogleMap API also did not work how I wanted it to; I originally wanted the api to show you an interactive map of where your item location was, but I had to change it to a static picture
 - From as much as I could find out this is due to JavaFX's webkit being out of date to the point GoogleMaps deems it to be a security risk. To avoid this I would have had to install and create my own Java Chromium Embedded Framework (JCEF). To avoid this I tried to force a specific version of chrome on the webView, but this still wasn't allowing the map to load properly. The creation and execution of a JCEF seems too demanding at the current moment, if I have time I will come back to this and try and fix everything.
- CheckoutController successfully integrate the Stripe Payment API

- I do not have the API call any real payment processing calls, rather just connecting the API and retrieving a unique session token that could be used to do so
- Additionally the CheckOutController now also has cart functionality
 - During my presentation you could only check out one item at a time, but now you're able to add multiple items into your cart and buy them all at once
 - The main caveat being that if you add an item to the cart you will be unable to see it in the main menu to ensure data integrity
 - If I have time I would also like to extend this into the database so that if two people have the same item in the cart, they cannot enter a race condition and or have the other person buy a product that has already been sold
- Within the ListingCreateController I also have the Google Map API geocode a string location and convert it to a longitude and latitude
 - It will also change the value of a users input so if they mistype it will enter a real location
 - It will also do checks and change the location to the closest possible real location to what was entered, and if it's unable to find something deemed worthy a listing cannot be created until one is given
 - You're able to upload pictures for you listings now
 - Unexpended error with uploading pictures and they aren't being showing
 - It seems to happen most commonly when a WEBP file is converted
 - For now I have an error being thrown to show it cannot be uploaded

Structure

- The structure has not

BackLog Of Work

- Finish the remaining scenes
- Strong Password Enforcement
- Have filtering on the main screen
- Seller Ratings/Reviews if there is time
- Overall UI improvements
 - Scene transitions being smoother visually

- Scene layouts looking nicer
- Easier to read and see what is happening without being overwhelmed
- Ensure admin app works and has CRUD functionality
- Fix visual bugs and bugs in general
 - Mainly with the issue of people uploading an image and it not appearing
- More testing – I have been doing this with JUnit
- CSV Invoices
 - If I have time for this I would also like to add a section on the admin app to view these invoices (have it act as a mini database)
- Bidding
- Possibly deploy on AWS/Azure
